

Revised Top 50 OHLCV-Only Trading Strategies

Executive Summary

This revision removes the strategies that are inherently multi-asset and cannot be implemented from one instrument's own history alone—**cross-sectional momentum, dual momentum, and pairs trading**—and replaces them with **RSI(2) mean reversion, TTM Squeeze breakout, and the Elder Impulse System**, all of which are single-asset and executable from one symbol's OHLCV stream. The result is a ranked list in which **all 50 strategies are implementable on a single asset**, with ten entries explicitly verified against primary PDF sources that contain usable implementation detail. ¹

The highest-confidence evidence still favors **trend-following and time-series momentum families**. In a century-scale study across 67 markets, an equal-weighted combination of 1-, 3-, and 12-month time-series momentum signals was profitable in each decade since 1880; the full-sample exhibit reports 7.3% annualized excess return net of 2/20 fees and simulated costs with a 0.76 Sharpe ratio, and the paper's construction is simply "long rising markets, short falling markets." ²

At the same time, this report penalizes strategies that are easy to overfit. That matters because the academic literature is mixed: the Brock-style moving-average and breakout families were historically influential, but a clean out-of-sample retest on the DJIA from 1987–2011 found no persistent predictive power for the original 26-rule set, and broad literature reviews conclude that profitability is highly dependent on market, execution costs, parameter choice, and testing discipline. ³

Methodology and Ranking Criteria

The ranking uses a deliberately simple score: **empirical efficacy** weighted most heavily, then **popularity in literature and practice**, then **robustness to overfitting**. In practice, this means strategies with long-sample support, low parameter count, and repeatability across markets rise to the top; strategies that depend on discretionary drawing, fragile thresholds, or context-sensitive pattern interpretation rank lower even when they are popular. ⁴

Assumptions are the ones you specified: asset class is left broad enough to include equities, FX, and crypto where the logic carries; **daily bars** are the default unless a rule is intrinsically intraday, such as ORB, VWAP, or session-based pivot logic. Empirical metrics are cited only where the underlying source explicitly reports them; otherwise they are treated as **unspecified** rather than inferred. ⁵

Verification Process and Replacements

For the ten singled-out strategies, I restricted the verification set to **English PDFs on academic or institutional domains, or authoritative platform documentation in PDF form**, and required that the PDF itself contain at least one executable implementation element: an explicit input definition, a lookback/threshold, and/or a concrete signal rule such as a crossover, threshold breach, or divergence. PDFs that

were only high-level summaries, paywalled abstracts without visible rule logic, or vague educational brochures were excluded from the “verified” subset. The ten selected PDF-backed strategies therefore all point to documents that explicitly describe mechanics rather than merely naming the indicator. ⁶

The replaced strategies are listed explicitly because they fail the single-asset constraint in a strict sense: **cross-sectional momentum** requires a cross-asset ranking universe, **dual momentum** requires a relative-strength comparison across assets, and **pairs trading** requires at least one second asset to form a spread. They were replaced by **RSI(2)**, **TTM Squeeze**, and **Elder Impulse**, which preserve the spirit of systematic momentum/mean-reversion/trend timing while remaining operational from one asset’s OHLCV history alone. ¹

Ranked Top 50

1. **Time-series momentum** uses a single asset’s own return history—typically 1-, 3-, and 12-month horizons on close-to-close returns—to go long when trailing excess return is positive and short or flat when negative; it tends to be crisis-helpful and persistent but can suffer when trends snap back sharply, and common variations combine horizons equally or lag execution by one month. ²
2. **200-day SMA absolute trend filter** uses **C** only on daily-monthly bars; go long or cover short when price crosses above the 200-bar SMA and exit long or short when it crosses below, a low-turnover trend rule with moderate lag and whipsaw risk, with common variations using 50/200 pairs, EMA substitutes, or month-end confirmation. **PDF source:** *Understanding Indicators in Technical Analysis* (Fidelity Investments Webinar Series; coauthor Charles D. Kirkpatrick II; year unspecified in PDF); extracted steps: input **C**, common horizons **50** and **200** bars, entry on price cross above SMA, exit/reverse on cross below, other parameters unspecified. ⁷
3. **Donchian channel breakout** uses **H, L, C** and usually 20–55 bars; buy when price closes above the upper channel and sell or short when it closes below the lower channel, a classic trend-following rule with strong upside convexity but frequent false starts in ranges, with Turtle-style fast/slow channels and asymmetric exits as common variants. ⁸
4. **Dual moving-average crossover** uses **C** and typically fast/slow windows such as 10/50, 20/100, or 50/200; buy when the fast average crosses above the slow average and exit/reverse on the opposite cross, a very popular medium-term trend rule whose main weakness is sideways-market whipsaw, with EMA and percentage-filter variants common. **PDF source:** *Predictability of the Simple Technical Trading Rules: An Out-of-Sample Test* by Jiali Fang, Ben Jacobsen, and Yafeng Qin (2012); extracted

steps: compare short and long averages, use combinations **1-50, 1-150, 5-150, 1-200, 2-200**, optional **1%** filter, and for fixed-length rules ignore new signals for **10 days** after crossover. ⁹

5. **Trading-range breakout** uses **H, L, C** and usually 20–200 bars; buy when price rises above rolling resistance and sell when it drops below rolling support, a sparse but conceptually robust breakout rule that benefits from persistent trends yet underperforms in noisy consolidation. **PDF source:** *Predictability of the Simple Technical Trading Rules: An Out-of-Sample Test* by Jiali Fang, Ben Jacobsen, and Yafeng Qin (2012); extracted steps: support/resistance are rolling minimum/maximum prices, example rule **1-50** buys on a break above the previous 50-day high and sells on a break below the previous 50-day low, with **10-day** holding and optional **1%** filter in the Brock-style setup. ¹⁰
6. **Multi-horizon trend factor** is the single-asset adaptation of diversified trend following: combine several own-history trend signals, usually 1-, 3-, 6-, and 12-month close returns or moving-average states, and trade only when the aggregate score is positive or negative; it is usually more robust than any one horizon alone but slower to react to turning points. ¹¹
7. **52-week high breakout** uses **H, C** over roughly 252 trading days; the practical single-asset adaptation buys a decisive break or close near a new 52-week high and exits on failed breakout or trailing stop, offering strong momentum capture but elevated gap and exhaustion risk, with pullback-to-breakout and volume-confirmed variants common. The strongest academic evidence here is for the **52-week high effect** rather than pure single-name breakout timing, so this rank is intentionally below broader trend families. ¹²
8. **ATR or NATR volatility breakout** uses **H, L, C** and typically a 14–22 bar ATR; enter when price exceeds a recent range, moving average, or channel by a volatility-scaled threshold and exit with ATR-based trailing logic, which improves cross-asset portability but remains vulnerable to volatility spikes and post-breakout reversals. Common variations include Chandelier-style exits, NATR normalization, and ATR-multiplier tuning. ¹³
9. **MACD crossover** uses **C** with the usual **12/26/9** settings; it is bullish when MACD crosses above zero or above its signal line and bearish on the reverse, making it a trend-following momentum rule with decent smoothness but lag around inflections, with histogram and zero-line filters as common variants. **PDF source:** *Understanding Indicators in Technical Analysis* (Fidelity Investments Webinar Series; coauthor Charles D. Kirkpatrick II; year unspecified in PDF); extracted steps: input **C**, parameters **12/26/9** in standard implementations, buy on MACD line crossing above signal or zero, sell on the reverse, stronger signals occur farther from zero as noted in the PDF. ¹⁴
10. **ADX plus DI trend confirmation** uses **H, L, C**, usually over **14** bars; go long when **+DI** is above **−DI** and ADX indicates a real trend, commonly **>25**, and avoid or exit when ADX falls back toward non-trending levels, which makes the rule robust for regime filtering but somewhat late. **PDF source:** *Understanding Indicators in Technical Analysis* (Fidelity Investments Webinar Series; coauthor Charles D. Kirkpatrick II; year unspecified in PDF); extracted steps: inputs **H, L, C**, default period **14**, “strong trend” when **ADX > 25**, “no trend” when **ADX < 20**, and **+DI/−DI** provide directional context. ¹⁵
11. **Bollinger squeeze breakout** uses **C** and optionally **V**, usually **20** bars with **2σ** bands; enter after a low-volatility squeeze when price breaks the band structure in the direction of expansion, a popular breakout rule with good convexity but higher false-break risk without confirmation, with BandWidth

and volume filters as common variants. **PDF source:** *Understanding Indicators in Technical Analysis* (Fidelity Investments Webinar Series; coauthor Charles D. Kirkpatrick II; year unspecified in PDF); extracted steps: inputs are price-based bands around an SMA, tightening bands indicate low volatility and a likely sharp move, unusually wide separation can indicate trend exhaustion, and profit targets can be framed using swings within the envelopes; exact directional trigger parameters are otherwise unspecified in the PDF. ¹⁶

12. **RSI reversal** uses **C**, typically **14** bars; buy when RSI exits oversold territory or shows bullish divergence and sell when it exits overbought or shows bearish divergence, giving attractive short-horizon mean reversion in ranging markets but many false signals in strong trends, with threshold shifts like 80/20 or 60/40 as common variants. **PDF source:** *Understanding Indicators in Technical Analysis* (Fidelity Investments Webinar Series; coauthor Charles D. Kirkpatrick II; year unspecified in PDF); extracted steps: input **C**, traditional thresholds **70/30**, trend-context ranges **40–90** in bull markets and **10–60** in bear markets, and divergence between price and RSI can flag reversals. ¹⁷
13. **Stochastic oscillator reversal** uses **H, L, C**, commonly **5/3/3** or **14/3/3**; buy when the oscillator rises back above oversold or when %K crosses %D in oversold territory and sell on the symmetric overbought signal, which is effective in ranges but weak in runaway trends. **PDF source:** *Understanding Indicators in Technical Analysis* (Fidelity Investments Webinar Series; coauthor Charles D. Kirkpatrick II; year unspecified in PDF); extracted steps: inputs **H, L, C**, overbought/oversold levels **80/20**, buy when the oscillator crosses back above **20**, sell when it crosses back below **80**, and divergences are additional signals. ¹⁸
14. **Opening-range breakout** uses intraday **O, H, L, C, V**, usually the first **5–30 minutes** of the session; buy a break above the opening high and short a break below the opening low, a high-energy intraday breakout class with sizable execution sensitivity and slippage risk, with filters for “stocks in play,” relative volume, or time window. Empirically, one large U.S. equities study on 2016–2023 data reported that filtering to active “stocks in play” materially improved the strategy’s profile. ¹⁹
15. **VWAP mean reversion** uses intraday **H, L, C, V**; fade statistically stretched moves away from session VWAP back toward the benchmark or trade continuation after re-acceptance above or below VWAP, a widely used execution-aware intraday rule whose main edge depends on liquidity and disciplined session context. Common variations add standard-deviation bands, opening-range filters, or only trade with the prevailing trend. ²⁰
16. **Anchored VWAP support or resistance trading** uses **H, L, C, V** from a chosen anchor such as a swing high, low, earnings date, or breakout bar; buy pullbacks that hold above AVWAP in an uptrend and sell rallies that fail below it in a downtrend, a structurally intuitive trend rule that can overfit if anchors are chosen subjectively. Variations anchor to events, regime shifts, or multiple swing points. ²¹
17. **Keltner channel breakout** uses **H, L, C** and usually a **20-EMA** with **2×ATR** bands; buy closes above the upper channel and sell or short below the lower channel, which adapts better than pure price channels to changing volatility but still suffers in directionless regimes. Mean-reversion interpretations of the same bands are common in flatter markets. ²²

18. **RSI(2) mean reversion** uses **C** with a **2-bar RSI**, usually inside a broader trend filter; buy when RSI(2) falls below **10** in an uptrend and exit on rebound, or short overbought extremes such as **>90**, producing very short holding periods and good average trade frequency at the cost of gap risk and regime fragility. Variations shift thresholds to 5/95 or require a 200-day uptrend. 23

19. **Bollinger-band mean reversion** uses **C**, typically **20** bars and **2 σ** bands; fade closes near or outside the outer band back toward the middle band when trend strength is weak, a classic range strategy with favorable payoff in oscillatory markets but poor behavior during trend acceleration. Common variations add ADX or band-width filters to avoid fading breakouts. 24

20. **Ichimoku cloud breakout** uses **H, L, C** with the canonical **9/26/52** structure; buy when price and the faster lines regain a bullish position relative to the cloud and exit on cloud failure or opposite cross, giving a comprehensive but moderately parameter-rich trend system. Variations simplify to cloud-only bias, Tenkan-Kijun crosses, or multi-timeframe confirmation. 25

21. **Aroon trend switch** uses **H, L** and typically **14–25** bars; go long when Aroon-Up dominates Aroon-Down and the oscillator is positive, and reverse when the dominance flips, a decent early-trend detector with moderate noise around transitions. Variations use raw Aroon lines, the oscillator, or combine with price breakouts. 26

22. **Parabolic SAR stop-and-reverse** uses **H, L, C**; buy when SAR flips below price and sell when it flips above, which makes it attractive for mechanical trend riding but notoriously whippy in ranges, with acceleration-factor tuning as the key variation. 27

23. **Short-term close-to-close reversal** uses **C** only over 1–5 bars; fade unusually strong recent moves back toward the short-run mean, a strategy with strong historical anomaly roots but heavy exposure to microstructure noise, costs, and fast regime breakdown. Variations use z-scores of return, volatility scaling, or a longer-term trend filter so that only pullbacks in trend are faded. 28

24. **Gap fade** uses **O, H, L, C, V** on daily or intraday bars; short large upside gaps or buy large downside gaps when post-open price action fails to continue, a high-variance mean-reversion setup with news and liquidity sensitivity, with premarket volume and opening-range confirmation as common filters. 29

25. **Support and resistance breakout** uses **H, L, C** and sometimes **V**; buy a decisive break above a well-defined resistance shelf and exit on failed retest or opposite break, a pure price-action trend rule that can work well but loses robustness when levels are drawn too subjectively. Variations use horizontal levels, trend channels, or close-only confirmation. 30

26. **TTM Squeeze breakout** uses **H, L, C** and usually **20, 2.0, 20, 1.5, 20** for the Bollinger/Keltner/momentum stack; buy the first green “fired” state when momentum is above zero and rising, short when the squeeze fires with momentum below zero and falling, a strong single-asset replacement for dual-momentum-style timing with clear but more complex mechanics. Common variations alter the squeeze periods or use multi-timeframe confirmation. 31

27. **Darvas box breakout** uses **H, L, C**, often with **V** as confirmation; buy when price breaches the upper band of the active box and sell when it breaks the lower band, a structurally clean breakout rule that performs best in strongly trending names and poorly in broad chop. ³²

28. **Williams fractal breakout** uses **H, L** on five-bar structures; buy when price breaks above an identified bullish fractal and sell when it breaks below a bearish fractal, a neat trigger mechanism that needs context because isolated fractals are frequent and noisy. Variations add alligator, moving-average, or trend filters. ³³

29. **Support and resistance bounce** uses **H, L, C** and often **V**; buy reversals off well-tested support and sell reversals off resistance, a mean-reversion or swing approach with attractive local risk/reward but high dependence on level quality and confirmation. Variations use candle confirmation, oscillator divergence, or pivot confluence. ³⁴

30. **Elder Impulse System** uses **C** with a **13-day EMA** and **MACD-histogram**; buy when the longer trend is bullish and the intermediate timeframe turns green, and sell when the longer trend is bearish and the intermediate turns red, making it a clean single-asset replacement for relative-strength timing with lower turnover than very short oscillators. Variations change the dominant timeframe or the higher-timeframe trend proxy. ³⁵

31. **CCI correction strategy** uses **H, L, C** and the typical price implicitly, often with a weekly bias and daily entry; use higher-timeframe CCI to set direction and lower-timeframe CCI extremes to enter pullbacks, which improves selectivity but still requires trend persistence. Variations change the bias timeframe or the ± 100 thresholds. ³⁶

32. **Williams %R reversal** uses **H, L, C**, usually **14** bars; buy when %R recovers from deeply oversold and sell when it rolls over from overbought, a fast oscillator rule that behaves similarly to Stochastic but with simpler scaling, and is best filtered by trend or support/resistance context. Common variations alter thresholds or require a cross of the midpoint. ³⁷

33. **Money Flow Index reversal** uses **H, L, C, V**, usually **14** bars; buy when MFI reaches oversold conditions, typically below **20**, and turns higher or shows bullish divergence, and sell from overbought conditions, typically above **80**, or bearish divergence, a useful price-volume oscillator that can still pin in strong trends. **PDF source:** *Understanding Indicators in Technical Analysis* (Fidelity Investments Webinar Series; coauthor Charles D. Kirkpatrick II; year unspecified in PDF); extracted steps: inputs **H, L, C, V**, thresholds **20/80**, divergence versus price is a reversal cue, and the source explicitly warns that extremes alone are not enough without confirmation. ³⁸

34. **On-Balance Volume divergence and confirmation** uses **C, V**; trade with the prevailing price trend when OBV confirms new highs or lows, and fade or reduce risk when price makes a new extreme that OBV fails to confirm, a robust confirmation tool rather than a standalone alpha source. **PDF source:** *Understanding Indicators in Technical Analysis* (Fidelity Investments Webinar Series; coauthor Charles D. Kirkpatrick II; year unspecified in PDF); extracted steps: inputs **C, V**, OBV adds volume on up days and subtracts it on down days, negative divergence versus rising price is bearish, positive divergence versus falling price is bullish, parameters unspecified. ³⁹

35. **Accumulation/Distribution divergence** uses **H, L, C, V**; stay with the trend when price and A/D make matching higher highs or lower lows and look for stall or reversal risk when price diverges from A/D, a useful volume-context overlay with moderate robustness but weak standalone directionality. Variations use line breaks, moving-average smoothing, or combination with CMF. 40

36. **Chaikin Money Flow zero-line strategy** uses **H, L, C, V** over a lookback such as **20–21** bars; go long when CMF is positive and/or crosses above zero and bearish when negative, a compact volume-pressure filter that works best with price-trend confirmation. Divergences and smoothing changes are common variations. 41

37. **Price Volume Trend confirmation** uses **C, V**; trade in the direction of price when PVT confirms the move and treat PVT divergence as warning or reversal risk, a volume-confirmation method that is more sensitive to percentage price changes than OBV. Common variations add a moving average or zero-line filter to the PVT line. 42

38. **Relative-volume breakout** uses **C, V** and often **H, L**; buy breakouts that occur with volume materially above the recent average, which improves breakout selectivity and reduces false moves but can concentrate risk around event-driven volatility. Variations compare current volume to a 20–50 bar baseline or to time-of-day norms intraday. 43

39. **NR7 narrow-range breakout** uses **H, L, C** and optionally **V**; identify the narrowest range of the last seven bars and buy a move above that bar's high or sell below its low, a classic contraction-expansion setup with good short-term intuition but above-average whipsaw risk. Common variants use NR4, ATR-based stops, or trend and CCI/Aroon qualifiers. 44

40. **Pivot-point reversal or breakout** uses prior-period **H, L, C** and current **O/H/L/C** intraday; trade rejections from pivot support/resistance for mean reversion or trade clean breaks for continuation, a very popular intraday framework whose efficacy is highly session- and market-structure-dependent. Variations include classic, Camarilla, Woodie's, and multi-session pivots. 45

41. **KAMA adaptive crossover** uses **C**, with Kaufman's recommended **KAMA(10,2,30)** common; go long when price or a faster adaptive average rises above KAMA and exit when it loses KAMA, yielding a trend rule that adapts to noise better than many fixed MAs but is still parameter-sensitive. Variations use KAMA slope, dual KAMA, or KAMA as a regime filter only. 46

42. **MAMA-FAMA adaptive crossover** uses **C**; buy when MAMA crosses above FAMA and sell on the opposite cross, an adaptive trend rule designed to reduce lag in cycling markets but less extensively validated than simpler MA systems. Common variations tune fast and slow limits or use ATR and trend filters around the crossover. 47

43. **TRIX crossover** uses **C**, typically around **30** bars; buy when TRIX rises through zero or its signal line and sell on the reverse, which emphasizes smoothed trend momentum and helps suppress noise at the cost of extra lag. Variations shorten the period for faster markets or combine TRIX with a higher-timeframe trend filter. 37

44. **Price Oscillator zero-line crossover** uses **C** with chosen fast and slow moving averages; buy when the oscillator rises above zero and sell when it falls below zero, a normalized MA-difference rule that

is simple and transparent but still whipsaw-prone in flat markets. Variations change average type, add signal lines, or require price-structure confirmation. ⁴⁸

45. **Rate-of-change continuation** uses **C**, typically **10–20** bars; buy when ROC turns positive after a pullback or when positive momentum re-accelerates, and exit when ROC loses zero or diverges, a straightforward momentum rule with decent responsiveness but fragile standalone performance in noisy tapes. Variations use dual ROC horizons or volatility-normalized thresholds. ⁴⁹
46. **StochRSI reversal** uses **C** by applying Stochastics to RSI values, typically around **14/5/3**; buy when StochRSI exits oversold or %K crosses above %D and sell on the opposite extreme, giving very fast signals that can be useful for short-term trading but are especially vulnerable to overtrading. Variations smooth the oscillator more heavily or require trend confirmation. ⁵⁰
47. **Chandelier Exit trend trailing strategy** uses **H, L, C** and typically **22** periods with **3×ATR**; stay long while price remains above the long Chandelier level and reverse or exit when it breaks, a strong trend-riding exit framework whose main advantage is volatility-adjusted staying power rather than early entries. Variations adjust the ATR multiplier by asset volatility or pair Chandelier with StochRSI/CCI pullback entries. ⁵¹
48. **Engulfing-pattern reversal** uses **O, H, L, C**; trade bullish or bearish engulfing patterns with next-bar confirmation and nearby support/resistance context, a highly popular price-action rule with mixed academic evidence and meaningful dependence on filtering. Common variations require trend exhaustion, higher volume, or a fixed holding period. ⁵²
49. **Hammer and shooting-star reversal** uses **O, H, L, C**; buy confirmed hammers near support and sell confirmed shooting stars near resistance, a compact candlestick reversal approach with attractive local risk/reward but fragile standalone edge. Variations add gap location, ATR stop sizing, or momentum divergence. ⁵²
50. **Doji or morning/evening-star reversal** uses **O, H, L, C**; trade indecision or multi-candle reversal structures only after confirmation, which makes them useful as contextual triggers but weak as fully standalone systems, especially after costs. Their low rank reflects the fact that academic evidence on candlestick profitability is mixed to negative across several major markets. ⁵³

Summary Table

The table below compresses the ranked list into the attributes you requested. Signal families and required fields follow the same source material used in the ranked entries above. ⁵⁴

Rank	Name	Primary signal type	Typical timeframe	Required OHLCV fields
1	Time-series momentum	Trend/momentum	Daily-monthly	C
2	200-day SMA filter	Trend	Daily-monthly	C
3	Donchian channel breakout	Trend	Daily-weekly	H, L, C

Rank	Name	Primary signal type	Typical timeframe	Required OHLCV fields
4	Dual moving-average crossover	Trend	Daily-weekly	C
5	Trading-range breakout	Trend/price-action	Daily-weekly	H, L, C
6	Multi-horizon trend factor	Trend/momentum	Daily-monthly	C
7	52-week high breakout	Momentum/price-action	Daily-weekly	H, C
8	ATR/NATR volatility breakout	Volatility/trend	Daily-weekly	H, L, C
9	MACD crossover	Trend/momentum	Daily-weekly	C
10	ADX + DI trend	Trend	Daily-weekly	H, L, C
11	Bollinger squeeze breakout	Volatility	Daily-weekly	C
12	RSI reversal	Mean-reversion/ momentum	Daily	C
13	Stochastic oscillator reversal	Mean-reversion/ momentum	Daily	H, L, C
14	Opening-range breakout	Volatility/price-action	Intraday	O, H, L, C, V
15	VWAP mean reversion	Mean-reversion/ volume	Intraday	H, L, C, V
16	Anchored VWAP support/ resistance	Trend/volume	Intraday-daily	H, L, C, V
17	Keltner channel breakout	Volatility/trend	Daily	H, L, C
18	RSI(2) mean reversion	Mean-reversion	Daily	C
19	Bollinger-band mean reversion	Mean-reversion/ volatility	Daily	C
20	Ichimoku cloud breakout	Trend	Daily-weekly	H, L, C
21	Aroon trend switch	Trend	Daily	H, L
22	Parabolic SAR	Trend	Daily	H, L, C
23	Short-term close-to-close reversal	Mean-reversion	Daily	C
24	Gap fade	Mean-reversion/price- action	Intraday-daily	O, H, L, C, V
25	Support/resistance breakout	Price-action	Daily-weekly	H, L, C

Rank	Name	Primary signal type	Typical timeframe	Required OHLCV fields
26	TTM Squeeze breakout	Volatility/momentum	Daily-intraday	H, L, C
27	Darvas box breakout	Price-action/trend	Daily-weekly	H, L, C, V
28	Williams fractal breakout	Price-action	Daily	H, L
29	Support/resistance bounce	Price-action/mean-reversion	Daily	H, L, C
30	Elder Impulse System	Trend/momentum	Daily-weekly	C
31	CCI correction	Mean-reversion/trend	Daily-weekly	H, L, C
32	Williams %R reversal	Mean-reversion	Daily	H, L, C
33	Money Flow Index reversal	Volume/mean-reversion	Daily	H, L, C, V
34	On-Balance Volume divergence	Volume	Daily	C, V
35	Accumulation/Distribution divergence	Volume	Daily	H, L, C, V
36	Chaikin Money Flow zero-line	Volume	Daily	H, L, C, V
37	Price Volume Trend confirmation	Volume	Daily	C, V
38	Relative-volume breakout	Volume/price-action	Daily-intraday	C, V
39	NR7 breakout	Volatility/price-action	Daily	H, L, C
40	Pivot-point reversal/breakout	Price-action	Intraday	H, L, C
41	KAMA adaptive crossover	Trend	Daily	C
42	MAMA-FAMA adaptive crossover	Trend	Daily	C
43	TRIX crossover	Momentum/trend	Daily	C
44	Price Oscillator zero-line crossover	Momentum/trend	Daily	C
45	Rate-of-change continuation	Momentum	Daily	C
46	StochRSI reversal	Mean-reversion/momentum	Daily	C
47	Chandelier Exit trend trail	Trend/volatility	Daily	H, L, C
48	Engulfing-pattern reversal	Price-action	Daily	O, H, L, C

Rank	Name	Primary signal type	Typical timeframe	Required OHLCV fields
49	Hammer/shooting-star reversal	Price-action	Daily	O, H, L, C
50	Doji or morning/evening-star reversal	Price-action	Daily	O, H, L, C

Open Questions and Limitations

The ranking is strongest where the literature and implementation manuals converge—especially on trend-following, moving averages, breakout channels, and major momentum oscillators. It is weaker for lower-ranked candlestick and some niche indicator strategies, where the evidence base is either market-specific, more practitioner-driven than academic, or explicitly mixed. That is why the report pushes trend, breakout, and deterministic momentum rules upward and leaves pattern-heavy or interpretation-heavy setups near the bottom. ⁵⁵

A final caveat is that some strategies with strong academic evidence—especially **52-week high**, **ORB**, and short-term reversal families—have evidence that is often strongest in a **cross-sectional** or highly filtered implementation, while the ranking here deliberately constrains them to **single-asset OHLCV-only** use. Where that gap exists, I have ranked the strategy conservatively and stated the adaptation explicitly rather than pretending the single-asset version inherits the full strength of the broader literature. ⁵⁶
